Core Switches and VLANs

Overview

What Is a Core Switch in Networking?

Unlike access switches, which connect directly to end-user devices, the core switch focuses on aggregating and routing.

Key Takeaways

VLANs in core switches segment network traffic, enhance security, and optimize performance by creating logical broadcast domains within the high-capacity backbone of a network.

VLA

N Functionality in Core SwitchesVLANs (Virtual Local Area Networks) allow core switches to logically separate devices into distinct broadcast domains, even if they are physically connected to the same switch or across multiple switches. This segmentation ensures that traffic from one VLAN does not interfere with another, reducing unnecessary broadcast traffic and improving overall network efficiency. Core switches use VLANs to manage traffic between aggregation switches and access switches, maintaining high-speed data flow across the network backbone.

Ns in Core SwitchesNetwork Segmentation: VLANs divide the network into logical groups, such as departments or services, which isolates traffic and prevents congestion from spreading across the entire network. This is particularly important in large enterprise networks where multiple departments share the same physical infrastructure. Enhanced Security: By isolating traffic, VLANs prevent unauthorized access between different network segments.

Devices in one VLAN cannot communicate with devices in another VLAN unless explicitly allowed through inter-VLAN routing, typically handled by the core switch or a Layer 3 device. Traffic Management and Performance Optimization: Core switches use VLANs to reduce broadcast domains, which minimizes unnecessary traffic and improves throughput.

VLA

Ns also allow for prioritization of critical traffic, such as VoIP or data center communications, enhancing Quality of Service (QoS) management. Simplified Network Management: VLANs enable administrators to reconfigure network segments via software without physically moving devices. This flexibility is crucial in core switches, which handle large volumes of traffic and require centralized management for scalability and redundancy.

Inter-VLAN RoutingCore switches often perform inter-VLAN routing using Layer 3 capabilities, allowing devices in different VLANs to communicate securely and efficiently. This is achieved through Switched Virtual Interfaces (SVIs) or routing engines within the core switch, which maintain high-speed connectivity while enforcing access controls.

Summary

In essence, VLANs in core switches provide logical segmentation, security, traffic optimization, and centralized management. They are fundamental for maintaining a scalable, high-performance, and secure network backbone, ensuring that the core switch can efficiently handle traffic between multiple network segments while supporting enterprise-level policies and services.

Best place to configure VLANs: Core Switch vs Peplink 3?

Best practice is to create VLANs on the core switch. It depends on what the VLAN is for. What is in it, what connects to it (and from where), and how secure it needs to be. Based on that, you

Accessing other switches from core switch

I have an old catalyst switch and I want to connect these 2 switches together. One of them will be used as core and the second will be used as acces sw. Normally I do it on new switches easily.
