Optical Amplifier LPO

Overview

LPO maintains the familiar pluggable form factor of traditional optical modules but eliminates the power-hungry DSP chip.

Key Takeaways

In LPO systems, the optical amplifier function is integrated via high-linearity transimpedance amplifiers (TIAs) and driver chips, enabling low-latency, power-efficient optical signal transmission without a DSP.

Overview of LPO Architecture

Linear Pluggable Optics (LPO) is a high-speed optical transceiver technology designed to reduce power consumption and latency by removing the digital signal processor (DSP) from the module. Instead of performing complex digital processing inside the module, LPO relies on: High-linearity driver chips to directly modulate the optical signal. Transimpedance amplifiers (TIAs) for photoelectric conversion and signal amplification.

Host-side Ser

Des (Serializer/Deserializer) for signal equalization and compensation. This architecture shifts signal processing from the module to the host device, making the module simpler, more efficient, and suitable for short-reach, high-density connections.

Role of Optical Amplifiers in LPO

In LP

O, the optical amplifier function is primarily handled by the TIA and driver combination: The driver chip converts electrical signals into optical signals with high linearity.

The TI

A amplifies the received optical signal after photodetection, ensuring sufficient signal strength for the host SerDes to process. Unlike traditional DSP-based modules, LPO does not perform digital equalization or error correction inside the module, so the analog performance of the amplifier and driver is critical for maintaining signal integrity.

Advantages of LPO

Low Power Consumption: Removing the DSP reduces module power by 30–50%, which is significant for large-scale data centers. Low Latency: Eliminating DSP processing steps reduces transmission latency, improving synchronization in AI/ML clusters. Cost Efficiency: DSPs account for 20–40% of module BOM cost; removing them lowers overall expenses.

Pluggable Flexibility: LPO retains the pluggable form factor, allowing hot-swapping and easy maintenance.

Limitations and Considerations

Shorter Transmission Distance: Without DSP-based equalization, LPO modules have higher bit error rates and are better suited for closed-system environments. Host Dependency: The host SerDes must provide high linearity and noise tolerance to compensate for the lack of in-module DSP. Ecosystem Maturity: LPO standardization is still developing, and multi-vendor interoperability may face challenges.

Bandwidth Constraints: As speeds increase from 112G to 224G per lane, maintaining signal integrity becomes more challenging due to analog limitations. Deployment ScenariosLPO is ideal for: AI/ML clusters and GPU fabrics, where low latency and high port density are critical. Hyperscale data centers, particularly for leaf–spine networks where host ASICs can manage signal conditioning.

Short-reach, high-density interconnects, typically within a single vendor ecosystem.

Conclusion

The optical amplifier in LPO is realized through high-linearity TIAs and driver chips, forming a purely analog signal path that reduces power, cost, and latency.

While LP

O offers significant advantages for modern data centers and AI deployments, careful consideration of host SerDes capabilities, link design, and ecosystem compatibility is essential for optimal performance.
