Optical attenuation is a consequence of optical fiber cables

Overview

What Is Attenuation in Fiber Optics and How Is It Measured?

Attenuation causes light to weaken as it travels through fiber optic cables. Learn why it happen.

Key Takeaways

Attenuation in optical fiber cables occurs primarily due to two mechanisms: Rayleigh scattering: This is caused by random inhomogeneities in the fiber material that are smaller than the wavelength of light, leading to the scattering of light as it travels through the fiber. Absorption: As light travels through the glass core, some of it is absorbed by the cladding, which contributes to the overall signal loss. These factors result in a gradual weakening of the light signal, which is measured as attenuation in decibels per kilometer (dB/km).
