Ordering of air switches in distribution boxes

Overview

Secondly, the switches should be arranged from left to right when installed, and the reserved position of the switch should be a whole position.

Key Takeaways

Air switches in distribution boxes should be arranged from left to right, with general switches first, followed by lighting, socket, and specialized circuits, each rated according to their load.

General Principles for Ordering

Main Switch: The general or main switch is typically a double-pole 32–63A air switch or isolation switch, placed at the leftmost or topmost position in the distribution box for easy access and control of the entire system. Lighting Circuits: Lighting circuits usually use 10–16A air switches. These are installed after the main switch and can be grouped into one or two circuits depending on the number of lights.

Socket Circuits: Standard outlets generally use 16–20A air switches, while high-power appliances (like kitchen or laundry equipment) may require 20A switches or separate circuits. Air Conditioning and Specialized Loads: Air conditioning units or other high-power devices typically use 16–25A air switches, often on dedicated circuits to prevent overload.

Three-

Phase Circuits: If a circuit is three-phase, a three-pole air switch is used. Ensure proper connection of phase, neutral, and ground lines according to the incoming supply. Physical Arrangement in the BoxLeft-to-Right Installation: Switches should be installed from left to right, starting with the main switch, followed by lighting, sockets, and specialized circuits.

Reserved Positions: Some distribution boxes have reserved positions, usually on the right side, for future expansion or additional circuits. Spacing and Accessibility: Ensure enough space for wiring, terminal access, and ventilation. Avoid overcrowding to maintain safety and ease of operation.

Wiring and Safety Considerations

Separate Bus Bars: Neutral, earth, and live lines should be separated and well-insulated. Circuit Labeling: Each switch should be clearly labeled to indicate its circuit for easy identification and maintenance. No Joints in Incoming Wires: Ensure incoming wires are long enough to reach terminals without splicing.

Phase and Neutral Cutoff: Use bipolar or 1P+N switches to cut off both phase and neutral in case of short circuits or leakage, ensuring safety.

Summary

The recommended sequence in a household distribution box is: Main switch → Lighting circuits → Socket circuits → Air conditioning/specialized circuits, with each switch rated according to its load. Proper left-to-right arrangement, labeling, and adherence to safety standards ensure efficient operation and protection of both people and electrical equipment.
