What are the seismic resistance requirements for network server racks

Overview

This article explores how seismic server racks protect data centers in earthquake zones, detailing the components, certifications, and engineering standards that define their role in resilience.

Key Takeaways

Network server racks must be structurally reinforced, anchored, and tested to withstand seismic forces according to standards like NEBS GR-63-CORE, IBC, and ASCE 7.

Key Standards and Codes

Seismic server racks are designed to comply with NEBS GR-63-CORE, which defines protection against vibration, shock, and earthquakes for telecommunications equipment, particularly in high-seismic zones (Zone 4) in the U. S. They also follow the International Building Code (IBC) and, in California, OSHPD regulations for healthcare and public facilities.

For nonstructural components, ASCE 7-22 Chapter 13 provides formulas to calculate horizontal seismic forces on equipment, considering factors like spectral acceleration, component importance, and height within the building.

Structural and Design Requirements

Reinforced Frames: Racks use high-tensile steel or fully welded frames to resist lateral and vertical forces, reducing flex points and vibration transfer. Anchoring Systems: Specialized floor anchoring mechanisms secure racks to the building structure, preventing tipping or displacement during tremors. Anchoring patterns and hardware must follow engineer-approved specifications.

Shock Absorption: Some racks include isolation pads or seismic platforms to dampen vibrations and reduce shock wave impact on sensitive electronics. Load Distribution: Seismic racks are designed to support higher loads than standard racks, often exceeding 2,000 pounds, without structural failure.

Seismic Design Considerations

Seismic Zones: Racks are rated according to seismic zones (1–4 in the U. S.), with Zone 4 representing the highest earthquake risk. Seismic Design Categories (A–F): Facilities are classified based on expected ground motion.

Categories B and higher require seismic force review for rack design. Soil Type: Soil classification affects rack design; if unknown, racks must meet Class D soil requirements to ensure safety. Installation Site: The building's floor slab, structural support, and raised floor layout influence anchoring and rack placement.

Testing and Validation

Truly seismic-rated racks undergo dynamic testing and performance-based evaluation to validate their ability to withstand multi-directional motion. Compliance is documented, and installation must follow these specifications to maintain long-term safety and functionality.

Summary

To meet seismic resistance requirements, network server racks must combine structural reinforcement, proper anchoring, shock absorption, and load capacity while adhering to NEBS GR-63-CORE, IBC, ASCE 7, and local seismic codes. Design must account for seismic zone, soil type, and building characteristics, and performance should be validated through testing and documented installation procedures.
