# Where to ground the switchgear busbar during a power outage

## Overview

Main Earth Busbar (MEB): The switchboard frame and enclosures should be connected to the MEB, which serves as a common grounding point.

## Key Takeaways

The switchgear busbar should be grounded to the main grounding system using an earthing switch or maintenance grounding device on the load side after all sources are isolated and verified de-energized. Key Steps for Safe Grounding1. Isolate All Power Sources: Before grounding, ensure that all incoming and outgoing feeders, circuit breakers, and disconnectors are opened and de-energized.

Verify isolation visually or using voltage detection devices to confirm the absence of electrical energy, as per OSHA 1910. 269 and NFPA 70E standards. 2.

Use Proper Grounding Devices: Connect the busbar to the station or switchgear grounding system using an earthing switch or a portable maintenance grounding device rated for the available fault current. This creates an equipotential zone, redirecting any accidental or induced currents safely to ground. 3.

Placement of Grounding: Load Side (Outgoing Side): Always ground the busbar on the load side of the circuit breaker and disconnector. This ensures that feeder cables and downstream equipment are safely at ground potential during maintenance. Power Side (Incoming Side): Typically, grounding is not installed on the incoming line side unless the upstream source is already isolated and grounded elsewhere.

Special interlocks and operational permits are required if grounding is applied here. 4.

### Multipoint Grounding for GIS or M

V Switchgear: For gas-insulated switchgear (GIS) or medium-voltage switchgear, use multipoint grounding with short conductors connecting the busbar to the main ground at multiple locations. This reduces impedance, mitigates transient overvoltages, and ensures low magnetic field intensity. 5.

Verify Grounding: After connecting the grounding device, confirm that the busbar is at ground potential using a properly rated voltage detector. Only then should maintenance personnel approach the switchgear.

### Safety Considerations

Always follow lockout/tagout procedures to prevent accidental re-energization. Ensure grounding conductors are secure, corrosion-free, and rated for the maximum fault current. Use interlocked earthing switches where available to prevent operation on live circuits.

Maintain a two-person supervision system for high-voltage operations to enhance safety. By following these procedures, the switchgear busbar can be safely grounded during a power outage, protecting both personnel and equipment while complying with international safety standards.
