Working principle of optocouplers

Overview

An optocoupler uses light to transfer signals from one circuit over to another. This guide shows you how they work and how to use them.

Key Takeaways

Optocouplers transfer electrical signals between isolated circuits using light, providing electrical isolation and protection from voltage spikes and noise.

Working Principle

An optocoupler, also called an opto-isolator, consists of two main components: a light-emitting diode (LED) on the input side and a photodetector (such as a phototransistor) on the output side. When an electrical signal is applied to the LED, it emits light, typically infrared, proportional to the input signal. This light travels across an optically transparent barrier inside the device and strikes the photodetector.

The photodetector responds to the light by allowing current to flow in the output circuit, effectively reproducing the input signal without any direct electrical connection.

When the LE

D is off, the photodetector remains non-conductive, preventing current flow, similar to an open switch.

Function

The primary function of an optocoupler is electrical isolation. By using light to transfer signals, it separates high-voltage or noisy circuits from low-voltage or sensitive circuits, protecting components such as microcontrollers from voltage spikes, electrical noise, or grounding issues. Optocouplers are widely used in: Power supply circuits to safely transfer signals between high-voltage and low-voltage sections.

Microcontroller interfaces to prevent damage from voltage surges. Sensor circuits to avoid noise interference from processing circuits. Control systems and communication equipment where clean signal transfer is critical.

Types

Optocouplers are classified based on their output device: Phototransistor optocouplers: Most common, where the phototransistor switches on/off based on LED light. Photodiode, phototriac, and logic output optocouplers: Used for faster response, AC control, or digital logic applications.

Summary

In essence, an optocoupler converts an electrical signal into light and back into an electrical signal, maintaining complete electrical isolation between input and output. This ensures safe signal transmission, protects sensitive electronics, and reduces interference in both analog and digital circuits.

These components are called optocouplers or optoisolators or simply optos, and they perform the crucial function of passing signals between isolated sections of circuitry. They use light to

Optocouplers Working Principle

Optocoupler Principle Optocouplers are used to isolate sections of a circuit that are incompatible in terms of the voltage levels or currents required. For example, they are used to

What Is Optocoupler | Opto-coupler Working And Application

Opto-coupler is also called photocoupler, optoisolator or optical isolator. An optocoupler is mainly used to prevent an electrical collision by isolating the circuit. This is also used to eliminate unwanted noises.

What Is an Optocoupler? Types, Working Principles, and Applications

An optocoupler is a tiny part that moves signals between circuits without letting electricity jump across. It uses light to do the job, which helps keep things safe. That way, noisy signals,

What are Optocouplers? Definition, construction and working of ...

Optocouplers are common component by which electrical isolation can be supplied between the input and output source. It is a 6 pin device and can have any number of photodetectors. Here, a beam of

Optocouplers | How it works, Application & Advantages

Despite their sophistication, the operational principle of optocouplers is relatively straightforward. The LED in the input circuit gets activated when a voltage is applied, causing it to

Optocoupler Tutorial for Beginners

In this guide, you''ll learn how they work and how you can use one in your own projects. Optocouplers are very useful when you need to isolate different sections of a circuit, for example in
